EN3551 Assignment 2

Application of 2D-DCT for image compression

Due on or before: Monday, October 16, 2023

1 Introduction and General Guidelines

This programming assignment is concerned with the application of 2D-DCT to compress digital images.

Section 2 contains a general overview of the theory used in this assignment, followed by Section 3 and Section 4, which contains the specific tasks for the assignment.

Submit a report containing your solutions, diagrams, and explanations for each task. Briefly explain/justify how you obtained each of your answers. This will help us determine your understanding of the problem whether or not you got the correct answer. Moreover, in the event of an incorrect answer, we can still try to give you partial credit based on the explanation you provide. You may append your MATLAB codes as an appendix of this report.

2 Theoretical Background

2.1 Preliminaries

We can write the 1D-DCT (type 2 version) of a 1D signal x[n] as [1];

$$C(k) = \sqrt{\frac{2}{N}}\alpha(k)\sum_{n=0}^{N-1} x[n]\cos\left(\frac{(2n+1)k\pi}{2N}\right)$$
(1)

and the 2D-DCT of an array(2D-signal) x[m, n] of size $N \times N$ as;

$$C(i,k) = \frac{2\alpha(i)\alpha(k)}{N} \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} x[m,n] \cos\left(\frac{(2m+1)i\pi}{2N}\right) \cos\left(\frac{(2n+1)k\pi}{2N}\right) \quad 0 \le i,k \le N-1.$$
(2)

Here

$$\alpha(k) = \begin{cases} \frac{1}{\sqrt{2}}; & k = 0\\ 1; & 1 \le k \le N - 1 \end{cases}$$
 (3)

The 2-D inverse DCT (IDCT) is given by,

$$x[m,n] = \frac{2}{N} \sum_{i=0}^{N-1} \sum_{k=0}^{N-1} \alpha(i)\alpha(k)C(i,k) \cos\left(\frac{(2m+1)i\pi}{2N}\right) \cos\left(\frac{(2n+1)k\pi}{2N}\right) \quad 0 \le m, n \le N-1.$$
(4)

Matlab commands dct2 and idct2 can be used for 2-D DCT and IDCT evaluations respectively. A frequently useful 2-D DCT deals with 8×8 data blocks.

$$C(i,k) = \frac{\alpha(i)\alpha(k)}{4} \sum_{m=0}^{7} \sum_{n=0}^{7} x[m,n] \cos\left(\frac{(2m+1)i\pi}{16}\right) \cos\left(\frac{(2n+1)k\pi}{16}\right) \quad 0 \le i,k \le 7. \quad (5)$$

Among the 64 DCT coefficients defined by (5), the coefficient with (i, k) = (0, 0) is found to be

$$C(0,0) = \frac{1}{8} \sum_{m=0}^{7} \sum_{n=0}^{7} x[m,n]$$
(6)

This is proportional to the average value of the signal, making it the DC coefficient. Other C(i,k) with $(i,k) \neq (0,0)$ are AC coefficients.

If one regards the resulting DCT block $C(i, k), 0 \le i, k, \le 7$ as an 8×8 matrix and denote it by \mathbb{C} , then (5) implies that

$$\mathbf{C} = \frac{1}{4} \sum_{m=0}^{7} \sum_{n=0}^{7} x[m, n] \mathbf{B}_{m,n}$$
 (7)

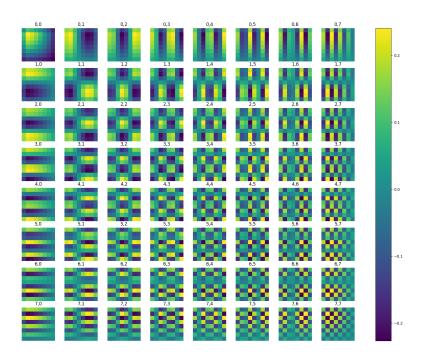

Here the $\mathbf{B}_{m,n}$'s are the 8×8 basis matrices formed only by cosine functions and depend only on indexes m, n. From (7) we see that the 2-D DCT of a data block x[m, n] can be obtained as the weighted sum of basis matrices.

2.2 2D DCT is Energy preserving and Orthogonal

The energy of a 2-D signal x[m, n] is defined as the sum of the squares of all its components, i.e.,

Energy of
$$\{x[m,n]\} = \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} x^2[m,n]$$

Figure 1: Basis matrices $\mathbf{B}_{m,n}$ for each m,n

Using Eq. 4 and 5, one can compute as follows for real valued signals.

$$\begin{split} \text{Energy of } \{x[m,n]\} &= \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} x^2[m,n] \\ &= \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} x[m,n].x[m,n] \\ &= \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} x[m,n].\frac{2}{N} \sum_{i=0}^{N-1} \sum_{k=0}^{N-1} \alpha(i)\alpha(k)C(i,k) \cos\left(\frac{(2m+1)i\pi}{2N}\right) \cos\left(\frac{(2n+1)k\pi}{2N}\right) \\ &= \sum_{i=0}^{N-1} \sum_{k=0}^{N-1} C(i,k).\frac{2\alpha(i)\alpha(k)}{N} \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} x[m,n] \cos\left(\frac{(2m+1)i\pi}{2N}\right) \cos\left(\frac{(2n+1)k\pi}{2N}\right) \\ &= \sum_{i=0}^{N-1} \sum_{k=0}^{N-1} C(i,k).C(i,k) \\ &= \sum_{i=0}^{N-1} \sum_{k=0}^{N-1} C^2(i,k) \\ &= \text{Energy of } \{C[i,k]\} \end{split}$$

which means the 2-D DCT does not change the signal's energy. It also can be shown that the 2-D DCT is an *orthogonal transform* in the sense that the "inner products" of the basis

matrices $\{B_{m,n}\}$ (see Eq.7) satisfy,

sum (sum (
$$\mathbf{B}_{\mathbf{m},\mathbf{n}} \circ \mathbf{B}_{\mathbf{p},\mathbf{q}}$$
)) =
$$\begin{cases} 16 & \text{if } (m,n) = (p,q) \\ 0 & \text{otherwise} \end{cases}$$

where \circ denotes the pointwise multiplication.

2.3 2D DCT is Separable: A Cascade of two 1D DCTs

From Eq.2, it is observed that the quantities involving index i and those involving index k are separate from each other. Taking this as an advantage, one writes Eq. 2 as,

$$C(i,k) = \sqrt{\frac{2}{N}}\alpha(i)\sum_{m=0}^{N-1}\cos\left(\frac{(2m+1)i\pi}{2N}\right) \bullet \underbrace{\left(\sqrt{\frac{2}{N}}\alpha(k)\sum_{n=0}^{N-1}x[m,n]\cos\left(\frac{(2n+1)k\pi}{2N}\right)\right)}_{\text{1-D DCT for "signal" }\{\hat{C}(m,k)\} \text{ with index k fixed}}$$

In other words, the 2-D DCT can be formed in two simple 1-D steps: Perform 1-D DCT rowby-row for the input 2-D signal $\{x[m,n]\}$, resulting in an intermediate 2-D "signal" denoted by $\{\hat{C}(m,k)\}$; then perform 1-D DCT column by column for $\{\hat{C}(m,k)\}$ that yields the 2-D DCT $\{C(i,k)\}$.

If we regard $\{C(i,k)\}$ as a matrix $N \times N$ and denote it by $\mathbf{C}_{\mathbf{N}}$, then Eq. 8 implies that $\mathbf{C}_{\mathbf{N}} = \mathbf{D}_{\mathbf{N}} \mathbf{X} \mathbf{D}_{\mathbf{N}}^{\mathbf{T}}$ where $\mathbf{X} = \{x[m,n]\}$ and,

$$\mathbf{D_N} = \sqrt{\frac{2}{N}} \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \cdots & \frac{1}{\sqrt{2}} \\ \cos\left(\frac{\pi}{2N}\right) & \cos\left(\frac{3\pi}{2N}\right) & \cdots & \cos\left(\frac{(2N-1)\pi}{2N}\right) \\ \vdots & \vdots & \ddots & \vdots \\ \cos\left(\frac{(N-1)\pi}{2N}\right) & \cos\left(\frac{3(N-1)\pi}{2N}\right) & \cdots & \cos\left(\frac{(2N-1)(N-1)\pi}{2N}\right) \end{bmatrix}$$

In particular, for an 8×8 data block $\mathbf{X}_{\mathbf{block}}$, its 2-D DCT can be calculated as,

$$\mathbf{C_8} = \mathbf{D_8} \mathbf{X_{block}} \mathbf{D_8^T}$$

where

$$\mathbf{D_8} = \begin{bmatrix} 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 \\ 0.4904 & 0.4157 & 0.2778 & 0.0975 & -0.0975 & -0.2778 & -0.4157 & -0.4904 \\ 0.4619 & 0.0913 & -0.1913 & -0.4619 & -0.4619 & -0.1913 & 0.1913 & 0.4619 \\ 0.4157 & -0.0975 & -0.4904 & -0.2778 & 0.2778 & 0.4904 & 0.0975 & -0.4157 \\ 0.3536 & -0.3536 & -0.3536 & 0.3536 & 0.3536 & -0.3536 & -0.3536 & 0.3536 \\ 0.2778 & -0.4904 & 0.0975 & 0.4157 & -0.4157 & -0.0975 & 0.4904 & -0.2778 \\ 0.1913 & -0.4619 & 0.4619 & -0.1913 & 0.1913 & 0.4619 & -0.4619 & 0.1913 \\ 0.0975 & -0.2778 & 0.4157 & -0.4904 & 0.4904 & -0.4157 & 0.2778 & -0.0975 \end{bmatrix}$$

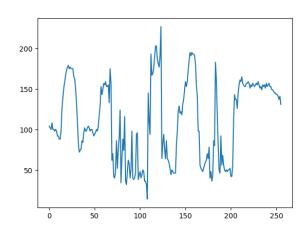

Notice that the matrix $\mathbf{D_N}$ is orthogonal, namely it satisfies $\mathbf{D_N}\mathbf{D_N^T} = \mathbf{D_N^T}\mathbf{D_N} = \mathbf{I_N}$.

2.4 De-correlation ability

Image compression is made possible by exploiting the redundancy present within the image, and the compression process fundamentally involves eliminating this redundancy from the image. The presence of correlation in a signal indicates that it can be further compressed. For illustration purposes, we examine the line in the 128th row of the 256×256 grey scale test image Lena (See Fig. 2a) which is shown in Fig. 2b.

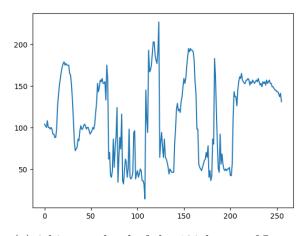

(a) Image Lena

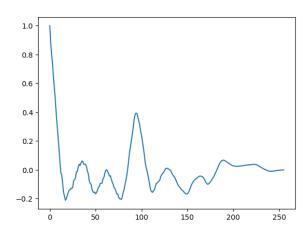

(b) 8-bit gray level of the 128th row of Lena

Figure 2

The 128th row of the image and its autocorrelation, which is a measure of how the signal is related to its shifted versions, are shown in Fig. 3a and 3b, respectively.

(a) 8-bit gray level of the 128th row of Lena

(b) Normalized autocorrelation of the signal

Figure 3

It is evident from Fig. 3b that the signal contains a great deal of redundancy because the correlation between the signal and its neighbouring samples is strong and decays rather slowly

with respect to the shift.

Now the 1-D DCT is applied to the above signal. The 1-D DCT $\{\hat{C}(128, k)\}$ and its autocorrelation are shown in Fig. 4a and 4b, respectively, which clearly demonstrates the decorrelation ability of the DCT.

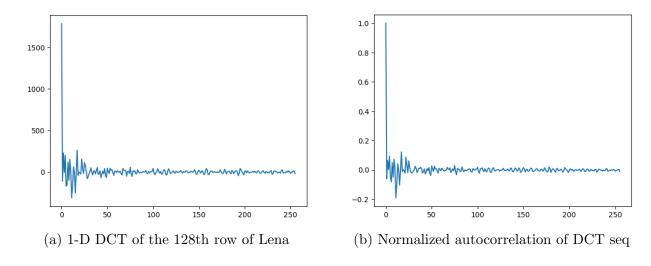

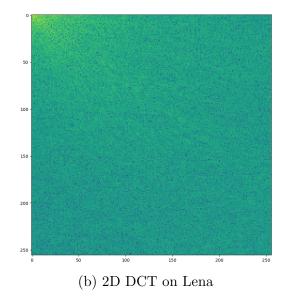

Figure 4

2.5 Energy compaction ability

The energy content of the signal, specifically the 128^{th} row of Lena, measures at 2.6909×10^6 . Since Discrete Cosine Transform (DCT) conserves energy, its application to this signal also results in an energy value of 2.6909×10^6 . Upon examination of Fig. 4a, it becomes evident that the majority of the energy in the DCT sequence is concentrated within a limited number of initial samples. In fact, the energy contained in the first 15 DCT samples totals 2.4786×10^6 , accounting for approximately 92.11% of the overall energy. It should be stressed that energy compaction is not just a coincidence that occurs in this particular case, but it is an intrinsic property of both 1-D and 2-D DCT.

Fig. 5a and 5b show image Lena and its 2-D DCT, which demonstrates the energy compaction property of the 2-D DCT. The lighter spots in Fig.5b represent samples of large values while the black dots represent samples of small values.

Figure 5

3 Procedure

3.1 2-D DCT - Application to Image Compression

Suppose the image to be compressed has size $M \times N$ with N being a multiple of 8. The image is divided into 8×8 blocks. The steps described below will be applied to each of these blocks. Let **B** be a representative 8×8 data block.

Step 1: Level-Off and 2-D DCT

Since DCT works better on pixel values from -128 to 127 rather than from 0 to 255, \mathbf{B} is levelled off by subtracting 128 from each entry. For illustration purposes, we take the (16,18)-th block of the 256×256 image Lena as matrix \mathbf{B} .

$$\mathbf{B} = \begin{bmatrix} 125 & 134 & 137 & 139 & 138 & 138 & 141 & 142 \\ 113 & 119 & 126 & 134 & 139 & 141 & 144 & 149 \\ 80 & 95 & 103 & 106 & 114 & 127 & 141 & 147 \\ 63 & 65 & 53 & 62 & 75 & 86 & 108 & 130 \\ 93 & 80 & 60 & 33 & 35 & 35 & 52 & 69 \\ 126 & 108 & 88 & 74 & 53 & 45 & 35 & 32 \\ 130 & 116 & 90 & 96 & 62 & 63 & 55 & 49 \\ 115 & 80 & 61 & 65 & 68 & 88 & 68 & 75 \end{bmatrix}$$

The modified data block after subtracting 128 from **B** is given by,

$$\tilde{\mathbf{B}} = \begin{bmatrix} -3 & 6 & 9 & 11 & 10 & 10 & 13 & 14 \\ -15 & -9 & -2 & 6 & 11 & 13 & 16 & 21 \\ -48 & -33 & -25 & -22 & -14 & -1 & 13 & 19 \\ -65 & -63 & -75 & -66 & -53 & -42 & -20 & 2 \\ -35 & -48 & -68 & -95 & -93 & -93 & -76 & -59 \\ -2 & -20 & -40 & -54 & -75 & -83 & -93 & -96 \\ 2 & -12 & -38 & -32 & -66 & -65 & -73 & -79 \\ -13 & -48 & -67 & -63 & -60 & -40 & -60 & -53 \end{bmatrix}$$

Applying 2-D DCT to $\tilde{\mathbf{B}}$, we obtain,

$$\mathbf{C} = \mathbf{T_8} \tilde{\mathbf{B}} \mathbf{T_8}^{\mathbf{T}}$$

$$\begin{bmatrix} -272.3750 & 17.1771 & 46.7784 & 4.2270 & 6.1250 \\ 182.5146 & -109.5361 & -28.0398 & -25.1231 & -8.9567 \\ 117.4897 & 19.1429 & -30.8911 & 15.7065 & 1.7309 \end{bmatrix}$$

$$= \begin{bmatrix} 182.5146 & -109.5361 & -28.0398 & -25.1231 & -8.9567 & -7.0036 & -6.1703 & 10.3445 \\ 117.4897 & 19.1429 & -30.8911 & 15.7065 & 1.7309 & 6.7882 & 5.4116 & -8.5788 \\ -23.4612 & 97.7162 & -0.0872 & -7.0795 & -1.0461 & 2.6980 & -2.9351 & 2.5446 \\ -48.3750 & -35.2958 & 27.0407 & 6.4060 & 4.1250 & -7.3615 & 3.5470 & 4.3781 \\ 15.8386 & -7.1745 & -7.9234 & -6.7518 & -0.5166 & 3.8019 & -8.3849 & -7.4654 \\ 0.4477 & 1.3348 & -5.5884 & 3.4787 & -4.6404 & -0.7361 & 4.6411 & 2.6707 \\ -3.6673 & 9.8948 & 6.2377 & -7.3148 & -7.0342 & 1.0065 & -0.6727 & 2.3138 \end{bmatrix}$$

Alternatively, one may apply MATLAB function 'dct2' to $\tilde{\mathbf{B}}$ to obtain \mathbf{C} .

Step 2: Quantization

A critical step in image compression is quantization and coding of the DCT coefficients in \mathbf{C} . The quantization may be achieved by converting matrix $\mathbf{C} = \{c_{i,j}\}$ to matrix $\mathbf{S} = \{s_{i,j}\}$ determined by,

$$s_{i,j} = \text{round}\left(\frac{c_{i,j}}{q_{i,j}}\right)$$
 (9)

-0.5799

0.2421

-8.4813

where $\mathbf{Q} = \{q_{ij}\}$ is a quantization matrix that may be selected according to a desired quality level of the compression. In the JPEG standard, subjective experiments involving the human visual system have produced their own quantization matrices. For example, with a quality level 50 (on a 1-to-100 scale) we have,

$$\mathbf{Q_{50}} = \begin{bmatrix} 16 & 11 & 10 & 16 & 24 & 40 & 51 & 61 \\ 12 & 12 & 14 & 19 & 26 & 58 & 60 & 55 \\ 14 & 13 & 16 & 24 & 40 & 57 & 69 & 56 \\ 14 & 17 & 22 & 29 & 51 & 87 & 80 & 62 \\ 18 & 22 & 37 & 56 & 68 & 109 & 103 & 77 \\ 24 & 35 & 55 & 64 & 81 & 104 & 113 & 92 \\ 49 & 64 & 78 & 87 & 103 & 121 & 120 & 101 \\ 72 & 92 & 95 & 98 & 112 & 100 & 103 & 99 \end{bmatrix}$$

Quantization matrices of other quality levels can be obtained by multiplying the above standard quantization matrix by a scaling factor τ where,

$$\tau = \begin{cases} \frac{100 - \text{quality level}}{50} & \text{quality level} > 50\\ \frac{\text{quality level}}{50} & \text{quality level} < 50 \end{cases}$$

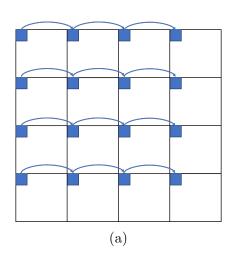

The scaled quantization matrix is then rounded and clipped to integer values between 0 and 255. With C obtained in Step 1 and $Q = Q_{50}$, the matrix S in Eq. 9 is found to be,

Evidently, if a quantization matrix with a reduced quality level is sued, then S will contain more zeros, thus a higher compression can be achieved at the cost of reduced image quality.

Step 3: Coding

The quantized matrix R is then converted by an encoder to a stream of binary data like {1001101...}. Detailed coverage of the coding process is beyond the scope of this experiment. Instead, we mention the following.

- The DC coefficients of the 8×8 blocks (see Fig. 6a) are encoded by a differential pulse-code modulation (DPCM) coding (also referred to as *DC prediction*).
- Because the location of the retained coefficients vary from block to block, the quantized AC coefficients are zigzag scanned (see Fig. 6b) and ordered into (run, level) pairs, where "level" means the value of a non zero coefficient, and "run" means the number of zero coefficients preceding it.
- These (run, level) pairs are entropy coded, that is, longer codes for less frequent pairs and vice versa.

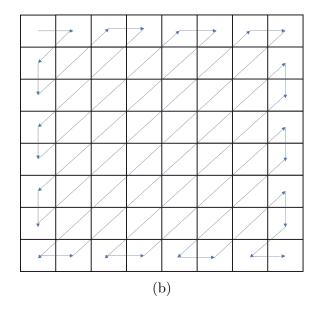

Figure 6

Step 4: Decompression

This is a step to be carried out at the receiver to reconstruct the image. It consists of the following three simple operations.

• Pointwise multiplication of matrix **S** with the quantization matrix **Q** to get an image block $\mathbf{R} = \mathbf{Q} \odot \mathbf{S}$. In our example, the **Q** matrix was taken to be \mathbf{Q}_{50} that yields,

• Apply 2-D inverse DCT to matrix \mathbf{R} . Note that this can be done by using the MATLAB command 'idct2'. Alternatively, it can be done using $\mathbf{D_8^TRD_8}$. This gives,

$$\mathbf{E} = \mathbf{D_8^TRD_8}$$

$$= \begin{bmatrix} 2.7181 & 2.1228 & 2.2693 & 4.2600 & 7.6484 & 10.8548 & 12.7203 & 13.3406 \\ -18.1034 & -10.6760 & -0.3337 & 7.7581 & 11.5839 & 12.5496 & 12.8140 & 13.1153 \\ -43.2294 & -34.5413 & -23.6264 & -15.8552 & -9.7946 & -0.4317 & 12.7343 & 23.0141 \\ -57.9809 & -58.9924 & -63.0283 & -67.8737 & -64.7907 & -46.4675 & -17.7381 & 4.4189 \\ -40.7650 & -50.9610 & -69.2674 & -88.8143 & -98.8380 & -92.2600 & -73.6202 & -57.6914 \\ 0.1073 & -12.7805 & -34.0432 & -57.0831 & -76.3805 & -89.4098 & -96.5154 & -99.3926 \\ 6.4904 & -8.6805 & -28.5866 & -43.2078 & -52.0062 & -61.1538 & -73.3190 & -83.0164 \\ -25.3942 & -44.5619 & -65.1582 & -70.4424 & -60.8203 & -50.0267 & -47.8854 & -50.9752 \end{bmatrix}$$

• Finally, the effect of the "level-off" operation in Step 1 is taken into account by adding 128 to the entries of the matrix E obtained above. This yields the reconstructed image block that mimics the image block **B** as,

$$\mathbf{B} = \mathbf{E} + 128$$

$$= \begin{bmatrix} 130.7181 & 130.1228 & 130.2693 & 132.2600 & 135.6484 & 138.8548 & 140.7203 & 141.3406 \\ 109.8966 & 117.3240 & 127.6663 & 135.7581 & 139.5839 & 140.5496 & 140.8140 & 141.1153 \\ 84.7706 & 93.4587 & 104.3736 & 112.1448 & 117.2054 & 127.5683 & 139.7343 & 151.0141 \\ 70.0191 & 69.0076 & 64.9717 & 60.1263 & 63.2093 & 81.5325 & 110.2619 & 132.4189 \\ 87.2350 & 77.0390 & 58.7326 & 39.1857 & 29.1620 & 35.7400 & 54.3798 & 70.3086 \\ 128.1073 & 115.2195 & 93.9568 & 70.9069 & 51.6195 & 38.5902 & 31.4846 & 28.6074 \\ 134.4904 & 119.3195 & 99.4134 & 84.7922 & 75.9938 & 66.8462 & 54.6810 & 44.9836 \\ 102.6058 & 83.4381 & 62.8418 & 57.5576 & 67.1797 & 77.9733 & 80.1146 & 77.0248 \end{bmatrix}$$

On comparing the block $\tilde{\mathbf{B}}$ with block \mathbf{B} (given in Step 1), we see $\tilde{\mathbf{B}}$ approximates \mathbf{B} quite well.

For an image of size $M \times N$ with both M and N being multiple-of-8 integers, the image is divided into $m \times n$ blocks with each block having size 8×8 , where m = M/8 and n = N/8. For a selected quality level, the steps described above is applied to each of these blocks, and the number of zeros contained in the \mathbf{R} matrices (see Step 4) is counted because the total number of zeros indicates how the image has been compressed. As expected, the use of reduced quality levels leads to a higher percentage of total zeros at the cost of a degraded image. Figures 7a, 7b, 7c and 7d show the results of the DCT-based compression method that was applied to image Lena of size 256×25 with 3 quality levels (50, 30, and 10).

3.2 Peak Signal to Noise Ratio (PSNR)

The PSNR is defined as;

$$PSNR = 20\log_{10}\left(\frac{\psi \max}{\sigma_e}\right) \tag{10}$$

where ψ_{max} denotes the maximum light intensity of the original image, which for an 8-bit digital image assumes the value of 255, and σ_e^2 denotes the mean squared error which can be evaluated using MATLAB by iterative using mean() over the two axes of a squared error matrix. The error matrix will be $I_{rec} - I_{original}$.

3.3 Tasks

- 1. Download 3 images assigned to your index number. You have to select one more image of your choice, which is not in the provided set of images.
- 2. Compress each of these images by the DCT-based method described above with three quality levels. The quality levels are also assigned based on your index number
- 3. Observe the results in terms of

(a) Original image

(b) Compressed, quality level = 50, zeros: 84.9%

(c) Compressed, quality level = 30, zeros: 88.8%

(d) Compressed, quality level = 10, zeros: 94.4%

Figure 7

- percentage of zeros,
- quality in terms of peak signal-to-noise ratio (see above), and
- visual quality of the compressed images as related to the quality level.
- 4. Some images are more difficult to compress than others in the sense that the visual (subjective) quality cannot be maintained as easily as others for a given compression ratio. Observe the compression results obtained in the task (2) from this perspective and explain why.

3.4 Useful MATLAB commands

- plot: plots a function
- fft: calculates the DFT
- dct2: returns the two-dimensional discrete cosine transform of the input
- idct2: returns the two-dimensional inverse discrete cosine transform of the input
- load: load contents from a file into a MATLAB workspace.
- norm: returns the norm of a vector input.
